

# High Performance Extrusion Coating EVA with Low Temperature Activation

Asia PLACE Symposium  
24-25 October 2006  
Shanghai, China

## Learning Outcomes

- Introduce AT Plastics, div of Celanese
  - Understand the effects of increasing %VA content in EVA resins
  - Specifically compare the adhesion performance of 16% VA and 28% VA lamination films
  - Troubleshoot typical difficulties encountered when extrusion coating EVA's with very high %VA content
- 

## **AT Plastics, div of Celanese**

- 
- Celanese ([www.celanese.com](http://www.celanese.com))
    - \$6 Billion diversified chemical company with many JVs in China
  - AT Plastics' Facility in Alberta, CANADA
  - Five High Pressure Autoclave Reactors
    - 145 kt annual capacity (EVA & LDPE)
  - Focus on Specialty Polymers (LDPE & EVA)
    - LDPE with melt index up to 2200
    - EVA grades from 6% VA to 40% VA
  - Excellent access to rail and ship ports
    - Ship to Asia from of Port of Vancouver
  - Technical Service Centre
    - Located in state of the art Celanese facility in Kentucky, USA
  - Represented in China by Cahota
- 

# Introduction

- What is Thermal Lamination Film ?
  - Step 1: LDPE or EVA is extruded onto substrate film (nylon, PET, BOPP)
  - Step 2: Film laminated to substrate stock
    - E.g. posters, school products, signs, book covers
- EVA is the established adhesive resin in the thermal lamination market
  - Versatile adhesion
  - Good processability
  - High gloss
  - Typically 15-18% vinyl acetate content

# The EVA Copolymer Structure

# ● Polymer Chain Branching in EVA's

- Long chain branching (LCB)

- Short chain branching (SCB)

- Net effect: Reduced crystallinity with increasing %VA (SCB)

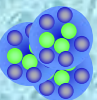

## Effect of Increasing % of VA

### → Polymer properties:

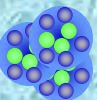

- More short chain branching
  - Less crystalline  
(More amorphous)
  - Lower melt temperature
  - More elastic as solid
  - Greater flexibility
  - Higher clarity and gloss
  - Higher density
    - (VA unit weighs more than Ethylene unit)
  - Increased polarity
    - VA more polar than ethylene
  - Increased toughness
- 

## Effect of Increasing % of VA

### → Application properties:

- Better adhesion to polar substrates
    - Aluminum Foil
  - Increased tackiness (Coeff of Friction)
    - “Blocking” - Pellets may stick together in a warm environment or under a heavy load
    - Wound film blocking concerns
      - Need good tension control
    - Molten resin sticking to chill rolls
  - Lower seal initiation temperature
    - Due to lower melt temperature and softening point
  - Increased tendency to degrade or form gels during extrusion
    - Generates acetic acid and “vinegar” odour
    - Acetic acid promotes crosslinking and gels
- 

# Property comparison 16% & 28% VA

## EVA Property

• Density

• DSC Melt Temp

• VICAT Soften Temp

• Tensile strength

• Elongation

## 16% VA

• 936 kg/m<sup>3</sup>

• 89 °C

• 62 °C

• 9 MPa

• 700%

## 28% VA

• 948 kg/m<sup>3</sup>

• 70 °C

• 43 °C

• 8 MPa

• 850%

# Materials

## Lamination Films:

- Thermal Lamination Film from two suppliers
  - EVA extrusion coated on primed PET and corona treated
- Two Extrusion Coating Resins
  - Ateva<sup>®</sup> 2821A = 28% VA, 25MI → call it **28**
  - Ateva<sup>®</sup> 1641 = 16% VA, 28MI → call it **16**
- Supplier "K" Structures: 0.25 mm PET / 0.5 mm EVA
  - **16K**      dynes=42      CoF=1.2      
  - **28K**      dynes=42      CoF=1.5      
- Supplier "L" Structures: 0.25 mm PET / 1 mm EVA
  - **16L**      dynes=44      CoF=1.1      
  - **28L**      dynes=44      CoF=2.6      

# Materials

## Substrates:

- Glossy paper substrates
- Offset Ink (solid print)

- Soy-based ink (solid print)

- Prints were about 1 month old and sealed in foil pouch

# Heat Seal Activation Comparison

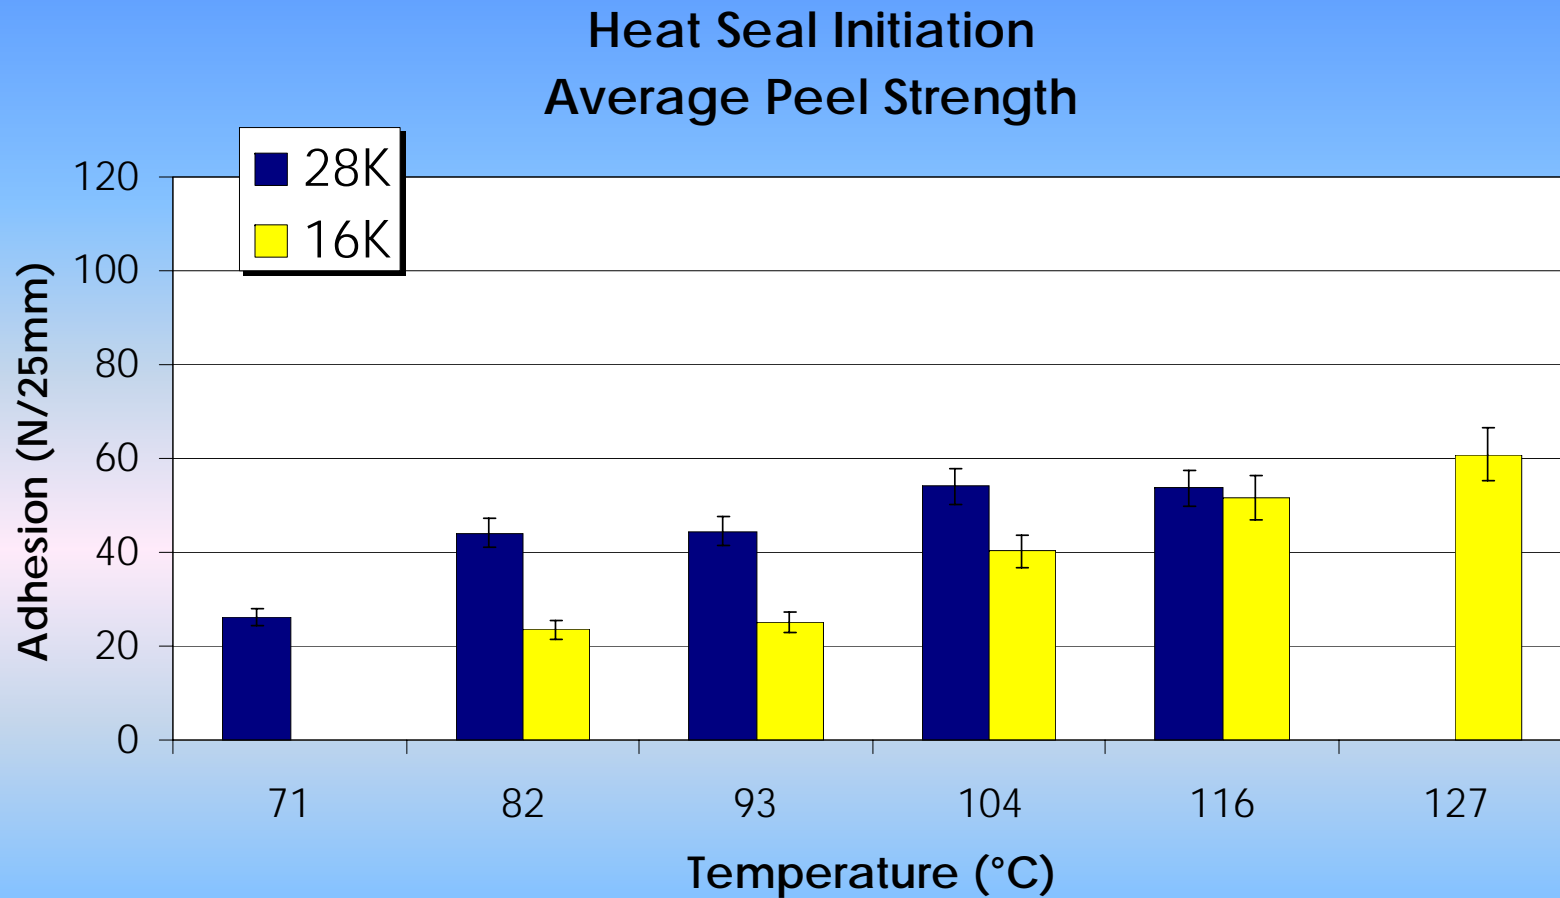

## Method:

- Heat seal film adhesive to adhesive
- 10 mm heat seal bars
- 138 kPa, 0.5 sec dwell
- Vary temperature from 71-127 °C
- Cut 2.5 cm strip and peel 180° on tensiometer @ 27 mm/min

# Heat Seal Activation – 16% & 28% VA

Supplier K Film: 0.25 mm PET/0.5 mm EVA

# Heat Seal Activation – 16% & 28% VA

## Heat Seal Initiation Average Peel Strength

Supplier L Film: 0.25 mm PET/1 mm EVA

# Optical Property Comparison

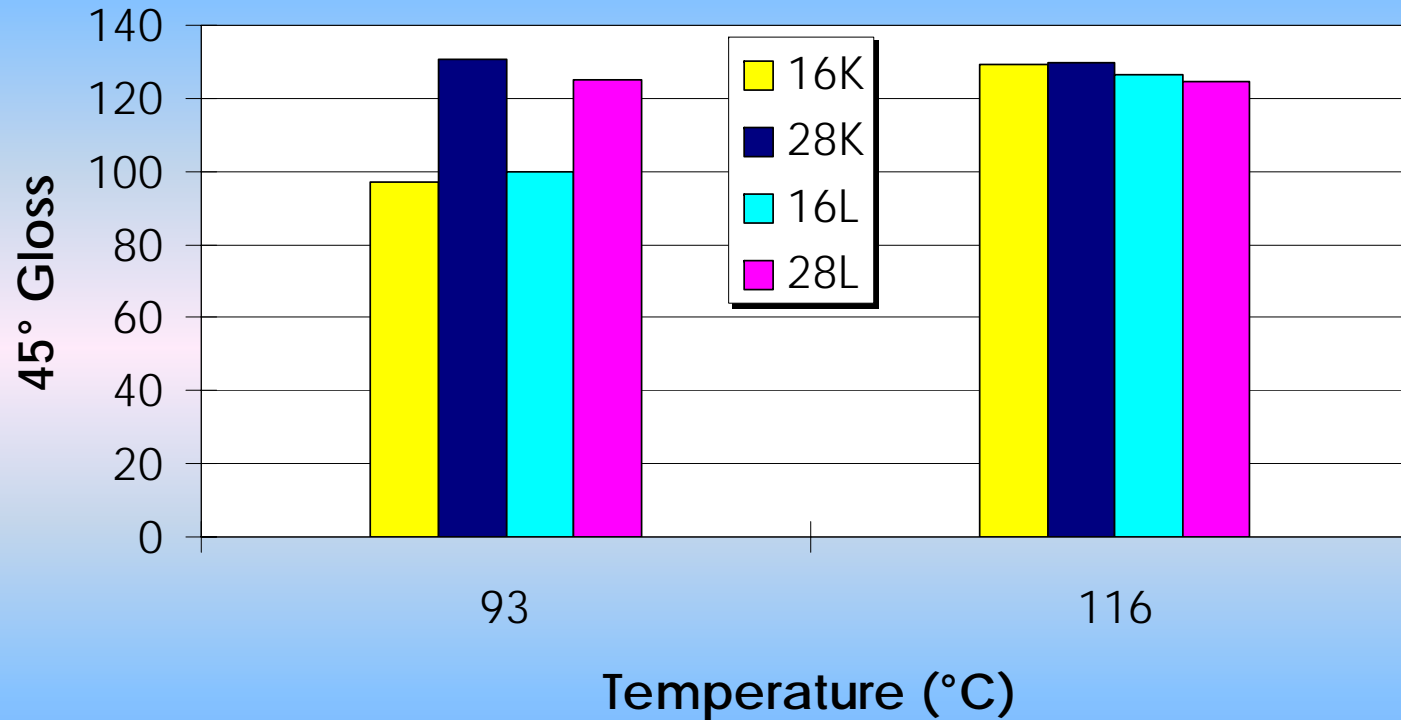

## Method:

- Heat seal film adhesive to adhesive
- Measure 45° gloss at surface of sealed structure
  - Although mainly influenced by PET gloss, adhesive resin has an effect
- Measure haze through sealed structure
  - Two temperatures selected
    - Common lamination temperature for 28% EVA ~93°C and for 16% EVA ~115°C

# Heat Seal Gloss Comparison

## Optical Properties - Gloss

# Heat Seal Haze Comparison

Optical Properties - Haze

# ● Adhesion to Printed Substrates

## Method:

- Desktop pouch laminator
  - Constant speed and pressure
  - Vary temperature from 71-127 °C
- Samples then peeled 1 hour after the lamination
- Cut 25 mm strip and peel on tensiometer 127 mm/min
  - 180° Peel Configuration
  - Max. load and average load between limits recorded
  - Peel strength reported in N/25 mm

0-5 = poor, 5-10 = fair, 10-15 = good, 15+ = excellent

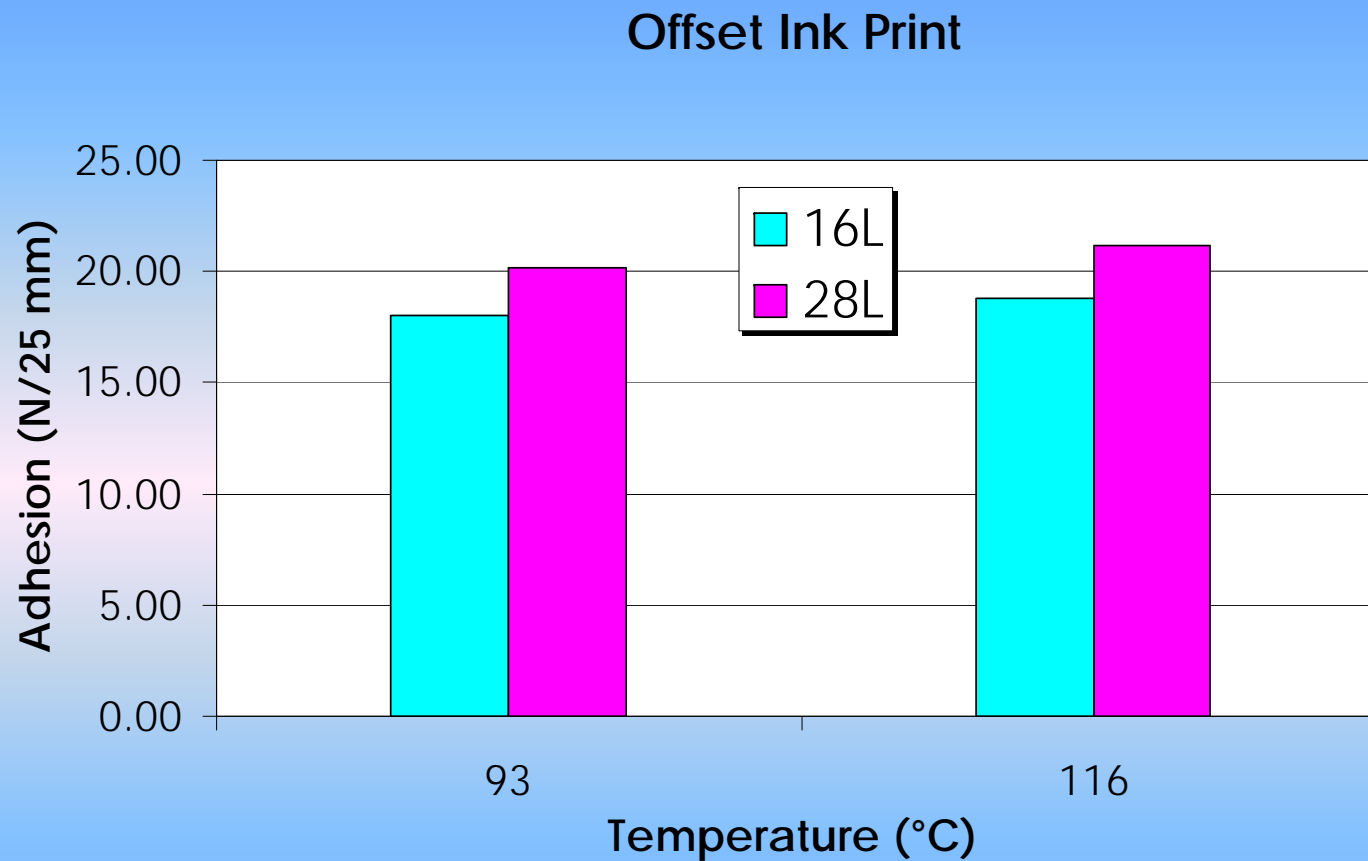

# Results on offset ink

Offset Ink Print

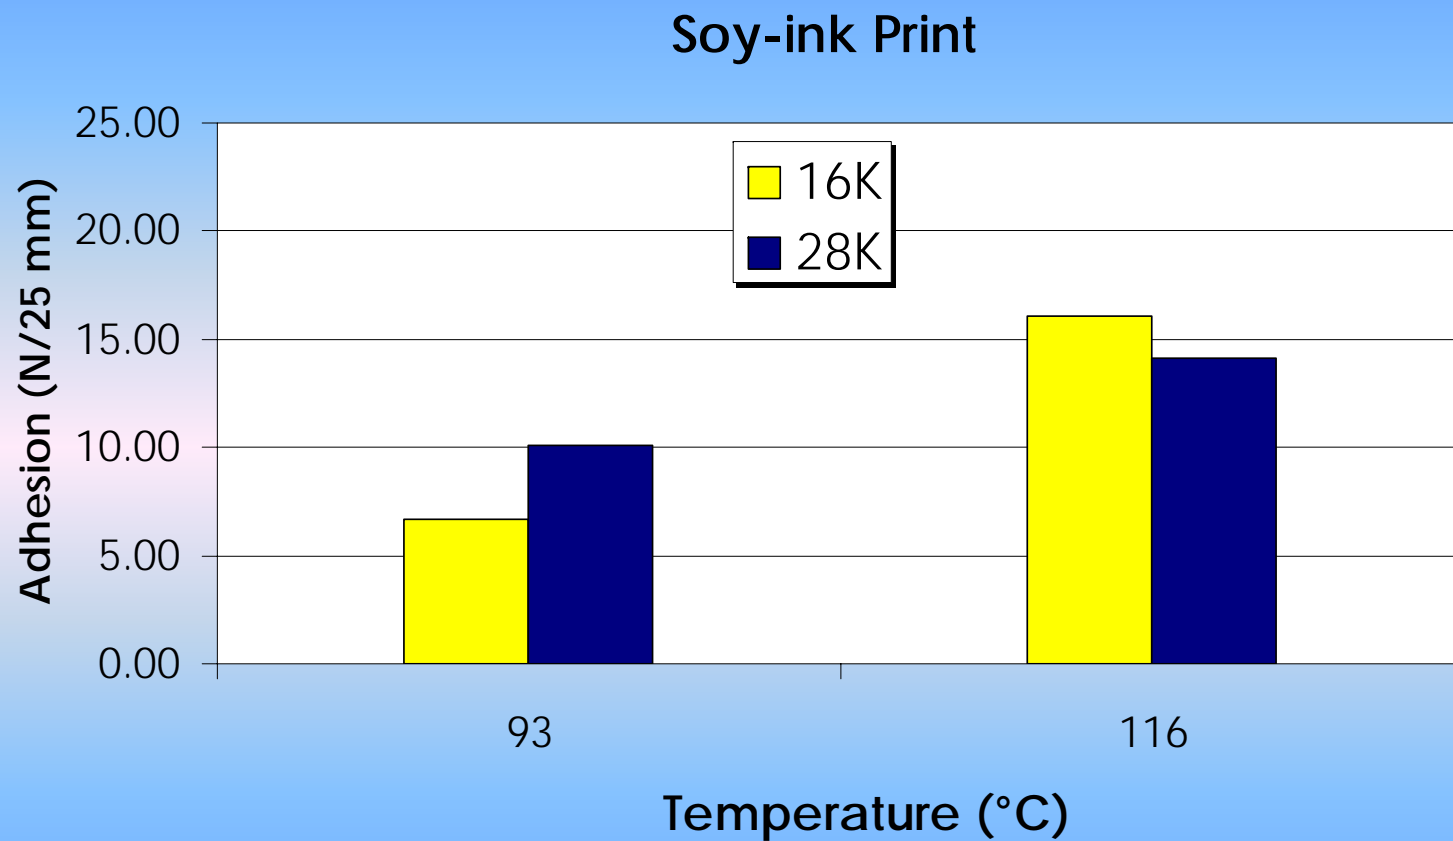

Supplier K Film: 0.25 mm PET/0.5 mm EVA

# Results on offset ink

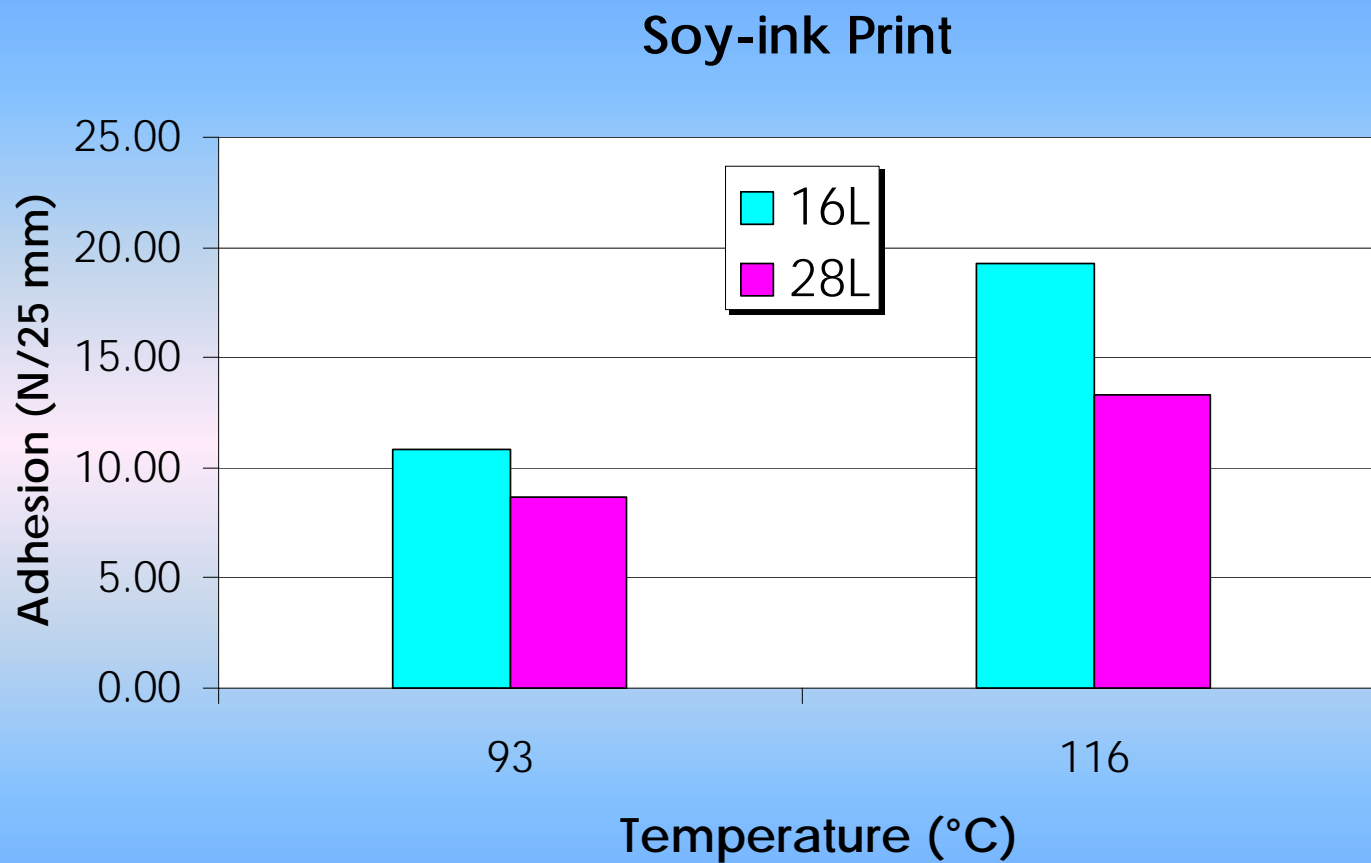

Supplier L Film: 0.25 mm PET/1 mm EVA

# Results on soy-based ink

Supplier K Film: 0.25 mm PET/0.5 mm EVA

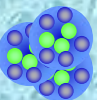

# Results on soy-based ink

Supplier L Film: 0.25 mm PET/1 mm EVA

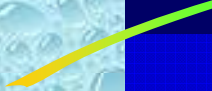

# Processing Guidelines for 28% EVA's

- Extrude 28% EVA's at lower temperature
    - Melt Temp for 16% EVA's typically 225 °C
    - Melt Temp for 28% EVA's recommended at 215 °C
      - To minimize gels after long run times
  - Minimize Chill Roll Sticking
    - Heat of melt - Could reduce melt temperature. However, watch for lowered adhesion properties.
    - Temperature of chill roll - Reduce chill roll temperature. Watch for condensation.
    - Efficiency of chill roll - Should use purified water to prevent fouling. Check for fouled water system.
- 

# Processing Guidelines for 28% EVA's

- 
- Minimize Chill Roll Sticking
    - Degree of wrap around chill roll - More wrap will allow more cooling. However, if too much wrap around, chill roll water does not have time to recover, and gradually warms up. ("recovery time of chill roll")
    - Angle of pull-off - steeper angle may help
    - Chill roll release agent in resin - Not usually used because of adhesion. Acts like slip agent, and migrates to interface.
    - Overcoat width - Sometimes resin is overcoated beyond edge of substrate film. Reduce if possible.
  - Minimize Wound Roll Blocking
    - Careful control of tension
    - Can use lower tension because of higher surface tack
- 

## Concluding Remarks

- Difference in melt/softening temperature: 20 °C
  - Difference in heat seal activation: 8 °C
    - MI difference may play a role
    - Adhesive thickness plays a role in bond strength
  - Optical properties of 28% EVA superior to 16% EVA at 93 °C
    - Just above melt temperature of 16% EVA at 93°C
  - Optical properties similar at 115 °C
    - Optical properties depend on quench rate
    - Fast solidification of melt allows less time for crystallization
    - Less crystallinity results in better gloss and lower haze
- 

# Concluding Remarks

- Adhesion to offset ink
  - Both 16% EVA and 28% EVA adhesion improves with increasing temperature
  - 28% EVA superior to 16% EVA at each temperature
- Adhesion to soy ink
  - Increasing temperature improved adhesion for each film
  - 16% EVA adheres better at 115 °C
  - 28% EVA adheres better at 93 °C but no advantage over 16% EVA at 115 °C
